What is PCA?

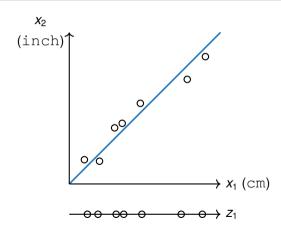

Why Dimensionality Reduction?

- Most datasets are high-dimensional (i. e. they have a large amount of features)
- Dimensionality reduction can be used for:
 - Lossy (!) data compression,
 - Feature extraction, and
 - Data visualization

Dimensionality reduction can help **speed up** learning algorithms substantially. Too many (correlated) features usually **decrease the performance** of the learning algorithm (curse of dimensionality).

Use Case I: Data Compression / Feature Extraction

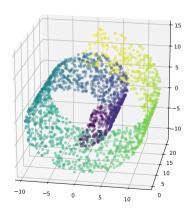

- The features inch and cm are closely related
- Problems:
 - Redundancy
 - More memory is needed
 - Algorithms become slow
- **Solution**: Convert x_1 and x_2 into a new feature z₁ $(\mathbb{R}^2 \to \mathbb{R})$

PCA: Principal Component Analysis

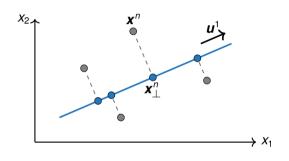

- PCA is an unsupervised algorithm
- PCA can be defined as the orthogonal projection of the data onto a lower dimensional linear space (the so-called principal subspace)
- Consider a dataset of N observations $extbf{\textit{X}} := \left\{ extbf{\textit{x}}^{1}, extbf{\textit{x}}^{2}, \ldots, extbf{\textit{x}}^{N} \right\}$
 - $\mathbf{x}^n \in \mathbb{R}^M \ (1 \leqslant n \leqslant N)$ is an *M*-dimensional feature vector
 - We want to project the data onto a space having dimensionality $D \ll M$, while maximizing the variance of the projected data $(\mathbb{R}^M \to \mathbb{R}^D)$

Goal: Remove dimensions which are the least informative of the data!

Wrap-Up

Why Dimensionality Reduction
Use Case I: Data Compression
Use Case II: Data Visualization
Further PCA Applications
What is PCA?

Orthogonal Projections (Case: $\mathbb{R}^2 o \mathbb{R}$)

- xⁿ denotes the original data point
- xⁿ_⊥ is the orthogonal projection of xⁿ onto the vector u¹

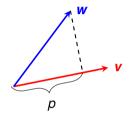

The goal is to find u^1 such that the variance of the projection is maximized!

Why Dimensionality Reduction Use Case I: Data Compression Use Case II: Data Visualization Further PCA Applications What is PCA?

Recall: Projection of Vectors

- Let $\mathbf{w}, \mathbf{v} \in \mathbb{R}^2$ be two vectors
- How is the (orthogonal) projection of **w** onto **v** defined?

$$p = \|\mathbf{w}\| \cos \angle(\mathbf{v}, \mathbf{w})$$
$$= \|\mathbf{w}\| \frac{\mathbf{v}^{\top} \mathbf{w}}{\|\mathbf{v}\| \cdot \|\mathbf{w}\|} = \frac{\mathbf{v}^{\top} \mathbf{w}}{\|\mathbf{v}\|}$$

- We will assume u^1 to be a unit vector, i. e. $||u^1|| = 1$
- $\frac{({\pmb u}^1)^{ op} {\pmb x}^n}{\|{\pmb u}^1\|}$ then reduces to the scalar product $({\pmb u}^1)^{ op} {\pmb x}^n$

Implementation of the PCA Algorithm FISHER's Linear Discriminant Analysis (FLDA) Wrap-Up

Maximum Variance Formulation (Ctd.)

- In the following we shall assume D=1 (i. e. we project the data onto a line defined by a unit vector \mathbf{u}^1)
- Each data point $\mathbf{x}^n \in \mathbb{R}^M$ is projected onto a scalar value $(\mathbf{u}^1)^\top \mathbf{x}^n \in \mathbb{R}$
- The **mean** of the projected data is $(\boldsymbol{u}^1)^{\top} \boldsymbol{\mu}$, where

$$\boldsymbol{\mu} := \frac{1}{N} \sum_{n=1}^{N} \boldsymbol{x}^{n}$$

• The **variance** of the projected data is given by (expand the square and simplify!):

$$\frac{1}{N} \sum_{n=1}^{N} \left((\boldsymbol{u}^{1})^{\top} \boldsymbol{x}^{n} - (\boldsymbol{u}^{1})^{\top} \boldsymbol{\mu} \right)^{2} = (\boldsymbol{u}^{1})^{\top} \boldsymbol{\Sigma} \boldsymbol{u}^{1}$$
 (1)

Maximum Variance Formulation (Ctd.)

• $\Sigma \in \mathbb{R}^{M \times M}$ is the **covariance matrix** defined by:

$$\Sigma := \frac{1}{N} \sum_{n=1}^{N} (\mathbf{x}^{n} - \boldsymbol{\mu}) (\mathbf{x}^{n} - \boldsymbol{\mu})^{\top}$$
 (2)

- We have to maximize the projected variance $(\boldsymbol{u}^1)^{\top} \boldsymbol{\Sigma} \boldsymbol{u}^1$ with respect to \boldsymbol{u}^1
- Constraint: $||u^1|| = 1$, otherwise u^1 grows unboundedly
- We have to solve the following LAGRANGE optimization problem:

$$\max_{\boldsymbol{u}^1} \left\{ (\boldsymbol{u}^1)^\top \boldsymbol{\Sigma} \boldsymbol{u}^1 + \lambda_1 (1 - (\boldsymbol{u}^1)^\top \boldsymbol{u}^1) \right\}$$
 (3)

Introduction / Maximum Variance Formulation
Formalization of the Problem
An Example
Properties of Covariance Matrices

Maximum Variance Formulation (Ctd.)

We have to solve

$$\frac{\partial}{\partial \boldsymbol{u}^1} \Big[(\boldsymbol{u}^1)^{\top} \boldsymbol{\Sigma} \boldsymbol{u}^1 + \lambda_1 \big(1 - (\boldsymbol{u}^1)^{\top} \boldsymbol{u}^1 \big) \Big] \stackrel{!}{=} \mathbf{0}$$

- This leads to the eigenvalue problem $\Sigma u^1 = \lambda_1 u^1$
- The equation tells us that $oldsymbol{u}^1$ must be an eigenvector of $oldsymbol{\Sigma}$
- If we left-multiply by $(\boldsymbol{u}^1)^{\top}$ and use $(\boldsymbol{u}^1)^{\top}\boldsymbol{u}^1=1$, we see: $(\boldsymbol{u}^1)^{\top}\boldsymbol{\Sigma}\boldsymbol{u}^1=\lambda_1$

The variance is maximized by setting u^1 equal to the eigenvector of Σ having the largest eigenvalue λ_1 . This eigenvector is the first principal component and its eigenvalue λ_1 is the variance it retains.

Introduction / Maximum Variance Formulatio
Formalization of the Problem
An Example
Properties of Covariance Matrices

Derivation of the Eigenvalue Problem

- Remember: $\frac{\partial}{\partial x} x^{\top} A x = 2Ax$, if **A** is a symmetric matrix
- Remember: $\mathbf{x}^{\top}\mathbf{x} = \|\mathbf{x}\|^2$, and $\frac{\partial}{\partial \mathbf{x}}\|\mathbf{x}\|^2 = 2\mathbf{x}$ (see exercise sheet #1)
- We get (because Σ is symmetric):

$$\frac{\partial}{\partial \boldsymbol{u}^{1}} \left[(\boldsymbol{u}^{1})^{\top} \boldsymbol{\Sigma} \boldsymbol{u}^{1} + \lambda_{1} (1 - (\boldsymbol{u}^{1})^{\top} \boldsymbol{u}^{1}) \right] = 2 \boldsymbol{\Sigma} \boldsymbol{u}^{1} - 2 \lambda_{1} \boldsymbol{u}^{1}$$

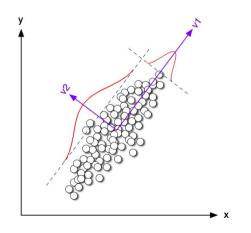

$$= 2 (\boldsymbol{\Sigma} \boldsymbol{u}^{1} - \lambda_{1} \boldsymbol{u}^{1}) \stackrel{!}{=} \mathbf{0}$$

• Setting this derivative to zero and reordering the terms yields the eigenvalue problem $\Sigma u^1 = \lambda_1 u^1$

Maximum Variance Formulation (Ctd.)

- Additional principal components can be defined in an incremental fashion
- Choose each new component such that it maximizes the remaining projected variance
- All principal components are orthogonal to each other
- Projection onto D dimensions:
 - The lower-dimensional subspace is defined by the D eigenvectors $\mathbf{u}^1, \mathbf{u}^2, \dots, \mathbf{u}^D$ of the covariance matrix Σ
 - These correspond to the *D* largest eigenvalues λ_1^{\star} , λ_2^{\star} , ..., λ_D^{\star}

Principal Components

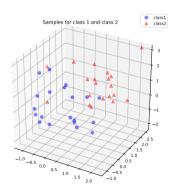

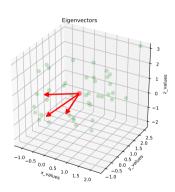

Here, v^1 is the first principal component. It captures the most variance of the data. The **second principal component** is given by \mathbf{v}^2 .

We see that both principal components are orthogonal, i.e.

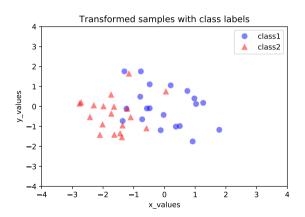

$$(\mathbf{v}^1)^{\top}\mathbf{v}^2 = 0.$$

PCA Example: Projection $\mathbb{R}^3 o \mathbb{R}^2$

PCA Example: Projection $\mathbb{R}^3 \to \mathbb{R}^2$ (Ctd.)

Covariance Matrix

Let the M features F_1, \ldots, F_M be given, then

$$\Sigma := \begin{pmatrix} \operatorname{cov}(F_1, F_1) & \operatorname{cov}(F_1, F_2) & \dots & \operatorname{cov}(F_1, F_M) \\ \operatorname{cov}(F_2, F_1) & \operatorname{cov}(F_2, F_2) & \dots & \operatorname{cov}(F_2, F_M) \\ \vdots & \vdots & \ddots & \vdots \\ \operatorname{cov}(F_M, F_1) & \operatorname{cov}(F_M, F_2) & \dots & \operatorname{cov}(F_M, F_M) \end{pmatrix} \in \mathbb{R}^{M \times M}$$
(4)

Remark:
$$cov(F_m, F_m) = V(F_m)$$
 for $m = 1, 2, ..., M$

Wrap-Up

FISHER's Linear Discriminant Analysis (FLDA)

Introduction / Maximum Variance Formulation Formalization of the Problem An Example Properties of Covariance Matrices

Properties of the Covariance Matrix

The covariance matrix Σ is computed according to:

$$\Sigma := \frac{1}{N} \sum_{n=1}^{N} (\mathbf{x}^{n} - \boldsymbol{\mu}) (\mathbf{x}^{n} - \boldsymbol{\mu})^{\top}$$
 (5)

Property ① The matrix Σ is a **square** $(M \times M)$ -matrix, where M is the number of features in the dataset

FISHER's Linear Discriminant Analysis (FLDA)

Properties of the Covariance Matrix (Ctd.)

Property 2 The matrix Σ is positive semi-definite, i. e.

$$\mathbf{x}^{\top} \boldsymbol{\Sigma} \mathbf{x} \geqslant 0 \quad \forall \mathbf{x} \in \mathbb{R}^{M}$$

Wrap-Up

It follows that all eigenvalues of Σ are **non-negative** and capture the **amount of variability** in an orthogonal basis given by the principal components

Property 4 The matrix Σ is always a **symmetric** matrix, i. e. we have $\Sigma^{\top} = \Sigma$, because $cov(F_i, F_j) = cov(F_j, F_i)$ for all features F_i and F_j

Wrap-Up

Property 6 The entries on the main diagonal of ${m \Sigma}$ are **non-negative** as they represent the variances of the individual features

PCA Algorithm

Input: Input data $\mathbf{X} = (\mathbf{x}^1, \mathbf{x}^2, \dots, \mathbf{x}^n) \in \mathbb{R}^{N \times M}$, number of dimensions D

Wrap-Up

Output: Projected data $\mathbf{Z} \in \mathbb{R}^{N \times D}$

- 1 Compute the sample set mean $\mu \longleftarrow \frac{1}{N} \sum_{n=1}^{N} \mathbf{x}^n$
- ² Compute the covariance matrix $m{\Sigma} \longleftarrow rac{1}{N} \sum_{n=1}^{N} m{(x^n \mu)} m{(x^n \mu)}^{ op}$
- $_3$ Eigendecomposition: Find matrices $m{U}, m{\Lambda} \in \mathbb{R}^{M imes M}$ such that: $m{\Sigma} = m{U} m{\Lambda} m{U}^ op$
- 4 Select the D eigenvectors with the largest eigenvalues to form the columns of ${m V}$
- 5 Project the data: $Z \longleftarrow XV$

Step 1: Computation of the Covariance Matrix

Step 1: Computation of Figure and Figure and

Step 3: Choice of the Number of Dimensions *D*

tep 4: Projection of the Data onto the Principal Subspace

Example: Computation of the Covariance Matrix

• **Example:** Let the following dataset be given:

$$\mathbf{X} := \{(1,4), (4,1), (1,1)\}$$

• We begin by computing the sample set mean μ of the dataset X

Wrap-Up

We obtain (by calculating the component-wise arithmetic mean):

$$\mu = \frac{1}{3} \left[\begin{pmatrix} 1 \\ 4 \end{pmatrix} + \begin{pmatrix} 4 \\ 1 \end{pmatrix} + \begin{pmatrix} 1 \\ 1 \end{pmatrix} \right] = \begin{pmatrix} 2 \\ 2 \end{pmatrix}$$

Example: Computation of the Covariance Matrix (Ctd.)

Wrap-Up

- We compute the outer products which we need to compute the covariance matrix:
- We get:

$$\boldsymbol{\varSigma}_1 := \begin{pmatrix} \boldsymbol{x}^1 - \boldsymbol{\mu} \end{pmatrix} \begin{pmatrix} \boldsymbol{x}^1 - \boldsymbol{\mu} \end{pmatrix}^\top = \begin{pmatrix} -1 \\ 2 \end{pmatrix} \begin{pmatrix} -1 & 2 \end{pmatrix} \quad = \begin{pmatrix} 1 & -2 \\ -2 & 4 \end{pmatrix}$$

$$\Sigma_2 := \begin{pmatrix} \mathbf{x}^2 - \boldsymbol{\mu} \end{pmatrix} \begin{pmatrix} \mathbf{x}^2 - \boldsymbol{\mu} \end{pmatrix}^{\top} = \begin{pmatrix} 2 \\ -1 \end{pmatrix} \begin{pmatrix} 2 & -1 \end{pmatrix} = \begin{pmatrix} 4 & -2 \\ -2 & 1 \end{pmatrix}$$

$$oldsymbol{\Sigma}_3 := \left(oldsymbol{x}^3 - oldsymbol{\mu}
ight)^ op = egin{pmatrix} -1 \ -1 \end{pmatrix} \left(-1 \ -1
ight) = egin{pmatrix} 1 & 1 \ 1 & 1 \end{pmatrix}$$

Step 1: Computation of the Covariance Matrix

Example: Computation of the Covariance Matrix (Ctd.)

Wrap-Up

- The covariance matrix is then computed by adding the matrices Σ_n (n=1,2,3)followed by component-wise division by the number of data points (here: N=3)
- The covariance matrix of **X** is:

$$\Sigma = \frac{1}{3} \left[\begin{pmatrix} 1 & -2 \\ -2 & 4 \end{pmatrix} + \begin{pmatrix} 4 & -2 \\ -2 & 1 \end{pmatrix} + \begin{pmatrix} 1 & 1 \\ 1 & 1 \end{pmatrix} \right]$$
$$= \begin{pmatrix} 2 & -1 \\ -1 & 2 \end{pmatrix}$$

Step 1: Computation of the Covariance Matrix
Step 2: Computation of Eigenvalues and Eigenvectors

Eigenvalues and Eigenvectors

• As a next step we have to find vectors \boldsymbol{u} and scalars λ which satisfy the equation

$$\Sigma u = \lambda u$$

• The vectors ${\pmb u}$ are called eigenvectors and the scalars λ are referred to as eigenvalues of the covariance matrix ${\pmb \Sigma}$

Wrap-Up

• The eigenvalues λ are the roots (German: *Nullstellen*) of the **characteristic polynomial** χ_{Σ} of Σ defined by:

$$\chi_{\boldsymbol{\Sigma}}(\lambda) := \det(\lambda \boldsymbol{I}_{M} - \boldsymbol{\Sigma}) \tag{6}$$

Example (continued): Computation of Eigenvalues

Wrap-Up

• The characteristic polynomial of Σ is given by

$$\chi_{\Sigma}(\lambda) = \det \begin{bmatrix} \begin{pmatrix} \lambda & 0 \\ 0 & \lambda \end{pmatrix} - \begin{pmatrix} 2 & -1 \\ -1 & 2 \end{pmatrix} \end{bmatrix} = \det \begin{pmatrix} \lambda - 2 & 1 \\ 1 & \lambda - 2 \end{pmatrix}$$

$$= (\lambda - 2)^2 - 1 = \lambda^2 - 4\lambda + 3$$

$$= (\lambda - 3)(\lambda - 1)$$

• Therefore, the eigenvalues are given by $\lambda_1 = 3$ and $\lambda_2 = 1$

Finding the corresponding Eigenvectors

- Let λ_i be an eigenvalue of Σ
- We want to find the corresponding eigenvectors **u** such that

Wrap-Up

$$\Sigma u = \lambda_j u \iff \Sigma u - \lambda_j u = 0$$
 $\iff (\Sigma - \lambda_j I_M) u = 0$

 Therefore, we have to find the solutions to the following homogeneous system of **linear equations** (see \Rightarrow here how this is done), where we set $\mathbf{A}_i := \mathbf{\Sigma} - \lambda_i \mathbf{I}_M$

$$A_i u = 0$$

Example (continued): Computation of Eigenvectors

We compute the eigenvectors for eigenvalue $\lambda_1 = 3$:

$$(\boldsymbol{\varSigma} - 3 \cdot \boldsymbol{I}_{M}) = \begin{pmatrix} -1 & -1 \\ -1 & -1 \end{pmatrix} \xrightarrow{-I+II} \begin{pmatrix} -1 & -1 \\ 0 & 0 \end{pmatrix} \xrightarrow{(-1)\cdot I} \begin{pmatrix} 1 & 1 \\ 0 & 0 \end{pmatrix}$$

Therefore, the eigenspace connected to eigenvalue $\lambda_1 = 3$ is given by

Wrap-Up

$$\mathcal{E}(3) = \left\{ t \cdot (1, -1)^\top : t \in \mathbb{R}, t \neq 0 \right\}$$

• Similarly, we obtain $\mathcal{E}(1) = \{t \cdot (1,1)^\top : t \in \mathbb{R}, t \neq 0\}$ for $\lambda_2 = 1$

Derivation of the PCA Algorithm Implementation of the PCA Algorithm FISHER's Linear Discriminant Analysis (FLDA)

Step 2: Computation of Eigenvalues and Eigenvectors

The Eigendecomposition of Σ

- Without loss of generality we can assume that the eigenvectors are normalized, i. e. $\|\mathbf{u}\| = 1$ (since $\mathbf{u}/\|\mathbf{u}\|$ is an eigenvector connected to the same eigenvalue)
- ullet The eigenvalues and eigenvectors of $oldsymbol{arSigma}$ can be used to decompose $oldsymbol{arSigma} \in \mathbb{R}^{ extit{M} imes extit{M}}$ into a product of three matrices $\Sigma = U \Lambda U^{\top}$, where $U \in \mathbb{R}^{M \times M}$ and $\Lambda \in \mathbb{R}^{M \times M}$
- *U* is obtained by stacking the **normalized** eigenvectors column-wise:

Wrap-Up

$$\boldsymbol{U} := \begin{pmatrix} | & | & & | \\ \boldsymbol{u}^1 & \boldsymbol{u}^2 & \dots & \boldsymbol{u}^M \\ | & | & & | \end{pmatrix} \in \mathbb{R}^{M \times M} \tag{7}$$

Derivation of the PCA Algorithm Implementation of the PCA Algorithm FISHER's Linear Discriminant Analysis (FLDA)

Step 2: Computation of Eigenvalues and Eigenvectors

The Eigendecomposition of Σ (Ctd.)

• $\Lambda := diag(\lambda_1, \ldots, \lambda_M)$ is a **diagonal matrix** with the eigenvalues on the diagonal:

Wrap-Up

$$oldsymbol{arLambda} := egin{pmatrix} \lambda_1 & 0 & \dots & 0 \ 0 & \lambda_2 & \dots & 0 \ dots & dots & \ddots & dots \ 0 & 0 & \dots & \lambda_M \end{pmatrix}$$

 If you put an eigenvector into column m of U, you have to make sure to put the corresponding eigenvalue in column m of Λ

Important: The order of eigenvectors and eigenvalues has to be consistent

Example (continued): The Eigendecomposition of Σ

Wrap-Up

• For $\lambda_1 = 3$ we choose

$$\boldsymbol{u}^1 := 1/\sqrt{2} \cdot (1, -1)^{\top}$$

• For $\lambda_2 = 1$ we choose

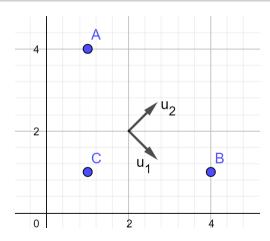

$$u^2 := 1/\sqrt{2} \cdot (1,1)^{\top}$$

Finally, we are able to write down the **eigendecomposition** of Σ :

$$oldsymbol{\Sigma} = egin{pmatrix} 2 & -1 \ -1 & 2 \end{pmatrix} = egin{pmatrix} \frac{1}{\sqrt{2}} & \frac{1}{\sqrt{2}} \\ -\frac{1}{\sqrt{2}} & \frac{1}{\sqrt{2}} \end{pmatrix} egin{pmatrix} 3 & 0 \\ 0 & 1 \end{pmatrix} egin{pmatrix} \frac{1}{\sqrt{2}} & -\frac{1}{\sqrt{2}} \\ \frac{1}{\sqrt{2}} & \frac{1}{\sqrt{2}} \end{pmatrix} = oldsymbol{U} oldsymbol{\Lambda} oldsymbol{U}^{ op}$$

Example (continued): Visualization Principal Components

Wrap-Up

Choice of D: Strategy 1

- The goal is to preserve as much variance as possible
- In the derivation we have seen that the eigenvalues represent the amount of variance captured by the respective principal components

Wrap-Up

• Again, we have a look at the $(M \times M)$ -matrix Λ

$$oldsymbol{\Lambda} = egin{pmatrix} \lambda_1 & 0 & \dots & 0 \ 0 & \lambda_2 & \dots & 0 \ dots & dots & \ddots & dots \ 0 & 0 & \dots & \lambda_M \end{pmatrix}$$

Introduction
Derivation of the PCA Algorithm
Implementation of the PCA Algorithm
FISHER's Linear Discriminant Analysis (FLDA)
Wrap-Ub

orithm Overview

p 4: Projection of the Data onto the Pr

Step 3: Choice of the Number of Dimensions *D*

Choice of *D*: Strategy 1 (Ctd.)

- Sort the eigenvalues in descending order
- Without loss of generality we assume that λ_1 is the largest, and λ_M the smallest eigenvalue (otherwise we can rearrange the elements in the matrices accordingly)
- Choose the smallest D which satisfies the inequality:

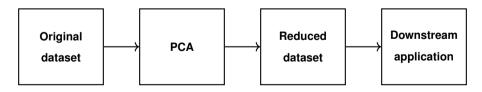

$$\frac{\sum_{j=1}^{D} \lambda_{j}}{\sum_{j=1}^{M} \lambda_{j}} \geqslant \gamma \qquad \gamma \in [0, 1]$$
(8)

• γ specifies the fraction of variance to be retained overall (this is a hyperparameter of the algorithm)

Step 1: Computation of the Covariance Matrix
Step 2: Computation of Eigenvalues and Eigenvectors
Step 3: Choice of the Number of Dimensions D

Choice of D: Strategy 2

- PCA is rarely used on its own, but in combination with a downstream application or classification task
 - Another possible strategy therefore is to choose *D* so as to **maximize the performance in this downstream application**

Introduction
Derivation of the PCA Algorithm
Implementation of the PCA Algorithm
FISHER's Linear Discriminant Analysis (FLDA)
Wrap-Ub

Step 1: Computation of the Covariance Matrix

Step 2: Computation of Eigenvalues and Eigenvectors

Step 3: Choice of the Number of Dimensions *D*Step 4: Projection of the Data onto the Principal Subspace

Projection of the Data

 We construct the matrix V (containing only the normalized eigenvectors connected to the D largest eigenvalues) which is given by

$$\boldsymbol{V} := \begin{pmatrix} \begin{vmatrix} & & & & \\ \boldsymbol{u}^1 & \boldsymbol{u}^2 & \dots & \boldsymbol{u}^D \\ | & | & & | \end{pmatrix} \in \mathbb{R}^{M \times D}$$
 (9)

• The projection of the data from M to D dimensions $(D \ll M)$ is then performed by matrix multiplication:

$$\mathbf{Z} := \mathbf{X}\mathbf{V} \in \mathbb{R}^{N \times D} \tag{10}$$

Step 4: Projection of the Data onto the Principal Subspace

Example (continued): Projection of the Data

• We choose to reduce **X** to one dimension and select the principal component $\boldsymbol{u}^1 = \frac{1}{\sqrt{2}} \cdot (1, -1)^{\top}$ connected to the larger eigenvalue $\lambda_1 = 3$

Wrap-Up

• V is therefore given by

$$\mathbf{V} := \begin{pmatrix} 1/\sqrt{2} \\ -1/\sqrt{2} \end{pmatrix}$$

• The projected data $\mathbf{Z} \in \mathbb{R}^{N \times D}$ is then obtained by matrix multiplication:

$$\mathbf{Z} := \mathbf{XV} = \begin{pmatrix} 1 & 4 \\ 4 & 1 \\ 1 & 1 \end{pmatrix} \begin{pmatrix} 1/\sqrt{2} \\ -1/\sqrt{2} \end{pmatrix} \approx \begin{pmatrix} -2.121 \\ 2.121 \\ 0 \end{pmatrix}$$

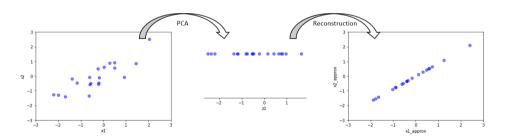

Step 4: Projection of the Data onto the Principal Subspace

Reconstruction from compressed Representation

It is possible to compute an approximate reconstruction of the data after having applied PCA:

Wrap-Up

$$\mathbf{X}_{\approx} := \mathbf{Z}\mathbf{V}^{\top} \tag{11}$$

Step 4: Projection of the Data onto the Principal Subspace

Example (continued): Projection of the Data

The reconstructed data is given by

$$\mathbf{X}_{\approx} := \mathbf{Z}\mathbf{V}^{\top} = \begin{pmatrix} -2.121 \\ 2.121 \\ 0 \end{pmatrix} \begin{pmatrix} 1/\sqrt{2} & -1/\sqrt{2} \end{pmatrix}$$

$$= \begin{pmatrix} -1.5 & 1.5 \\ 1.5 & -1.5 \\ 0 & 0 \end{pmatrix}$$

Wrap-Up

Section:

FISHER'S Linear Discriminant Analysis (FLDA)

Introduction

Derivation of the optimal 1D Projection

Dimensionality Reduction for Classification

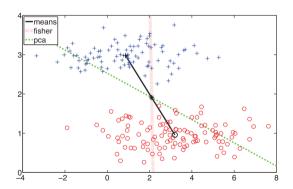

- We can use dimensionality reduction for classification
- However, using PCA often results in poor classification performance as it does not take the class labels into account
- Consider a labeled dataset comprising N training examples

$$\mathcal{D} := \{ (\mathbf{x}^1, y_1), (\mathbf{x}^2, y_2), \dots, (\mathbf{x}^N, y_N) \}$$

• We consider two-class problems only, i. e. $y \in \{1, 2\}$

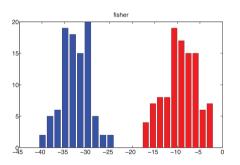

Goal: Find a 1D projection which maximizes the class separation

FLDA vs. PCA

cf. Murphy.2012, page 272

FLDA vs. PCA (Ctd.)

cf. Murphy,2012, page 272

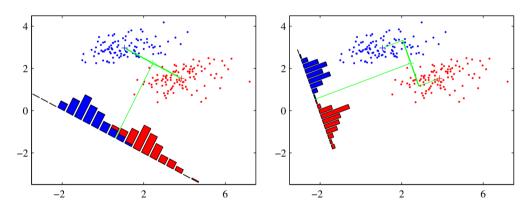

Projection of the Means

- We derive the optimal direction **w** for the two-class case
- The class-conditional means are defined as $(N_1 \text{ examples from } \mathcal{C}_1, N_2 \text{ from } \mathcal{C}_2)$

$$\mu^{1} := \frac{1}{N_{1}} \sum_{n: y_{n}=1} \mathbf{x}^{n} \quad \text{and} \quad \mu^{2} := \frac{1}{N_{2}} \sum_{n: y_{n}=2} \mathbf{x}^{n}$$
(12)

- Let $m_k := \mathbf{w}^{\top} \boldsymbol{\mu}^k$, k = 1, 2, be the projection of each mean onto the line \mathbf{w}
- One approach could be to maximize the distance between these means, i. e. $\max \mu^2 \mu^1$
- However, this does usually not result in a good model

Maximizing the Distance between the Means

cf. BISHOP.2006, page 188

Projected Variance

- Let $z_n := \mathbf{w}^{\top} \mathbf{x}^n$ be the projection of the data points onto the line \mathbf{w}
- The variance of the projected points belonging to class *k* is

$$s_k^2 := \sum_{n: y_n = k} (z_n - m_k)^2 \tag{13}$$

Goal: Find w so as to maximize the distance between the projected means, i. e. $m_2 - m_1$, while also ensuring the projected clusters are *tight*, i. e. have low variance

FISHER Criterion

FISHER criterion:

$$\mathfrak{J}_{F}(\mathbf{w}) := \frac{(m_{2} - m_{1})^{2}}{s_{1}^{2} + s_{2}^{2}} = \frac{\mathbf{w}^{\top} \mathbf{S}_{B} \mathbf{w}}{\mathbf{w}^{\top} \mathbf{S}_{W} \mathbf{w}}$$
(14)

We define the between-class scatter matrix S_B:

$$\mathbf{S}_{B} := \left(\boldsymbol{\mu}^{2} - \boldsymbol{\mu}^{1}\right) \left(\boldsymbol{\mu}^{2} - \boldsymbol{\mu}^{1}\right)^{\top} \tag{15}$$

We define the within-class scatter matrix S_W

$$\mathbf{S}_{W} := \sum_{n: \mathbf{v}_{n}=1} (\mathbf{x}^{n} - \boldsymbol{\mu}^{1}) (\mathbf{x}^{n} - \boldsymbol{\mu}^{1})^{\top} + \sum_{n: \mathbf{v}_{n}=2} (\mathbf{x}^{n} - \boldsymbol{\mu}^{2}) (\mathbf{x}^{n} - \boldsymbol{\mu}^{2})^{\top}$$
(16)

FISHER Criterion (Ctd.)

Proof: We proof that we can rewrite the FISHER criterion as in equation (14)

$$\mathbf{w}^{\top} \mathbf{S}_{B} \mathbf{w} = \mathbf{w}^{\top} (\boldsymbol{\mu}^{2} - \boldsymbol{\mu}^{1}) (\boldsymbol{\mu}^{2} - \boldsymbol{\mu}^{1})^{\top} \mathbf{w}$$

$$= (m_{2} - m_{1}) (m_{2} - m_{1}) = (m_{2} - m_{1})^{2}$$

$$\mathbf{w}^{\top} \mathbf{S}_{W} \mathbf{w} = \sum_{n: y_{n} = 1} \mathbf{w}^{\top} (\mathbf{x}^{n} - \boldsymbol{\mu}^{1}) (\mathbf{x}^{n} - \boldsymbol{\mu}^{1})^{\top} \mathbf{w} + \sum_{n: y_{n} = 2} \mathbf{w}^{\top} (\mathbf{x}^{n} - \boldsymbol{\mu}^{2}) (\mathbf{x}^{n} - \boldsymbol{\mu}^{2})^{\top} \mathbf{w}$$

$$= \sum_{n: y_{n} = 1} (z_{n} - m_{1})^{2} + \sum_{n: y_{n} = 2} (z_{n} - m_{2})^{2} = s_{1}^{2} + s_{2}^{2}$$

Maximization of the Objective

- We have to maximize equation (14) to find the optimal w
- For this we take the derivative of (14) with respect to **w** and set it to zero
- One can show that \mathfrak{J}_F is maximized when

$$\mathbf{S}_{B}\mathbf{w} = \lambda \mathbf{S}_{W}\mathbf{w}$$
 where $\lambda := \frac{\mathbf{w}^{\top} \mathbf{S}_{B}\mathbf{w}}{\mathbf{w}^{\top} \mathbf{S}_{W}\mathbf{w}}$ (17)

- Equation (17) is called generalized eigenvalue problem
- If S_W is invertible, we can convert it to the regular eigenvalue problem

$$\mathbf{S}_{W}^{-1}\mathbf{S}_{B}\mathbf{w}=\lambda\mathbf{w}\tag{18}$$

Maximization of the Objective

- We know $\mathbf{S}_{\!\scriptscriptstyle B}\mathbf{w} = \left(\mu^2 \mu^1\right) \left(\mu^2 \mu^1\right)^{\top}\mathbf{w} = \left(\mu^2 \mu^1\right) (m_2 m_1)$
- From equation (18) we have

$$\lambda \mathbf{w} = \mathbf{S}_{W}^{-1} (\mu^{2} - \mu^{1}) (m_{2} - m_{1})$$
 (19)

$$\mathbf{w} \propto \mathbf{S}_{W}^{-1} (\mathbf{\mu}^2 - \mathbf{\mu}^1)$$
 (20)

Since we only care about the directionality, and not the scale factor, we simply set

$$\mathbf{w} = \mathbf{S}_W^{-1} ig(\mathbf{\mu}^2 - \mathbf{\mu}^1 ig)$$

Self-Test Questions
Lecture Outlook

Summary

- Dimensionality reduction is important when we want to avoid the curse of dimensionality are or simply to visualize high-dimensional data
- It is defined as the orthogonal projection of the data onto a lower-dimensional (linear) subspace called the principal subspace
- We want to keep the dimensions with the most variance
- These dimensions are called principal components
- Many applications: Data visualization, eigenfaces, morphing, ...

Recommended Literature

1 PCA

- [Віѕнор.2006], chapter 12
- [MURPHY.2012], chapter 12.2

PLDA

- [BISHOP.2006], chapter 4.1.4
- [MURPHY.2012], chapter 8.6.3

(For free PDF versions, see list in GitHub readme!)

Self-Test Questions

- How can PCA be defined?
- What is the geometric relationship between the principal components?
- Outline the PCA algorithm!
- 4 How can you recover the original data? Will you get the exact same data?
- 6 Explain how the number of components / dimensions can be chosen!
- 6 Name some use cases of PCA!
- Describe what FLDA is! How do you find the optimal direction?

What's next...?

- I Machine Learning Introduction
- II Optimization Techniques
- III Bayesian Decision Theory
- IV Non-parametric Density Estimation
- V Probabilistic Graphical Models
- VI Linear Regression
- VII Logistic Regression
- VIII Deep Learning

- IX Evaluation
- X Decision Trees
- XI Support Vector Machines
- XII Clustering
- XIII Principal Component Analysis
- XIV Reinforcement Learning
 - XV Advanced Regression

Thank you very much for the attention!
